Understanding the Administrator’s Actions

Functional analysis of a blog website

1. Purpose of This Analysis

The purpose is to understand the needs of a blog website before developing it. Functional analysis helps identify the application’s general purpose, its context, the actors who use it, the actions they perform, and the system features needed to support those actions.

2. The Administrator as an Actor

An actor is a person or role that interacts with the application. The administrator is an actor who manages the blog through the administration area. The administrator’s exact permissions depend on the requirements of the application.

3. Common Administrator Actions

Manage articles: Create, view, edit, publish, unpublish, or delete blog articles.

Manage categories: Create, view, edit, or delete categories used to organize articles.

Manage users and access: Manage accounts and control permissions when these features are included.

Moderate comments: Review comments and remove spam or inappropriate content if the blog supports comments.

Maintain content quality: Check that published content is clear, relevant, and correctly organized.

4. From an Action to a Functionality

An action describes what an actor does. A functionality describes what the system must provide so that the actor can perform that action. For example, when the administrator wants to create an article, the system should provide a form to enter the article’s information and a way to save it.

Administrator action	Related system functionality
Create an article	The system allows the administrator to enter article details and save a new article.
Edit an article	The system allows the administrator to update an existing article.
Delete an article	The system allows the administrator to remove an article after confirmation.
Create a category	The system allows the administrator to add a category for organizing articles.
Review a comment	If comments are supported, the system allows the administrator to review or remove them.

5. Grouping Actions into Coherent Features

Related actions can be grouped into larger features. For example, creating, editing, and deleting articles belong to the feature “Article Management.” Creating, editing, and deleting categories belong to “Category Management.” Grouping actions this way makes the application’s requirements easier to understand and organize.

6. Conclusion

I understand that the administrator is an actor in the blog system. To analyze the administrator’s role, I identify the actions the administrator needs to perform, then connect each action to a system functionality. Finally, I group related functionalities into coherent areas, such as article management and category management. This analysis helps clarify what the administration area should provide before coding begins.

Scope note: The training page describes the learning goal as identifying the actors, their roles and actions, and grouping actions into coherent system features. It does not specify a required PDF format or confirm that every example above is part of the exact blog requirements. The examples are illustrative.
